Maria Francis

August 11, 2025

4/0/2025

# Sets

A set  $M$  is a well-defined collection of distinct objects.  
 $x \in M$  means  $x$  is a member of  $M$  otherwise  $x \notin M$ .  
 $N \subset M$  implies  $N$  is a subset of  $M$ , i.e. all the elements of  $N$  are also elements of  $M$ .

Examples –  $\emptyset = \{\}$ ,  $\{0\}$ ,  $\{0, 1\}$ ,  $\{A, B, C, \dots, Z\}$

4/0/2025

# Sets

$$\mathbb{N} \subseteq \mathbb{Z} \subseteq \mathbb{Q} \subseteq \mathbb{R} \subseteq \dots$$

Cardinality/Size – of a finite set  $X$  is the number of elements and is denoted by  $|X|$ .

Size can have different notions – size of an integer, number of bits needed to represent it, size of a binary string, its length.

Representation of sets can be done either by explicit listing of elements or by intervals or implicitly using formulas.

$M = \{x \in \mathbb{Z} : x^4 < 50\}$  describes the set of integers  $x$  for which  $x^4 < 50$  holds, or equivalently,  $M = \{-2, -1, 1, 2\}$ .  
 $M = \{0, 1\}^{12}$  – elements in  $M$  can either be written as a 12-bit binary string or as a vector  $(b_1, b_2, \dots, b_{12})$  where each  $b_i \in \{0, 1\}$ .

4/0 / 2025

# Set Operations

$M \cup N$  - union of two sets

$M \cap N$  - intersection of sets

$M \setminus N$  - set difference

$M \times N$  - Cartesian product of two sets

$M^n$  - n-ary product

$\mathcal{P}(M)$  - power set

4/0 / 2025

## Intuition on size of numbers – what is practical and what is not!

One can easily store one terabyte –  $10^{12} \approx 2^{43}$  bits.

On the other hand, a large amount of resources required to store one extra million bytes,  $\approx 2^{63}$  bits are impossible.

Same with computing steps :  $< 2^{40}$  steps/CPU core is easily doable.

$2^{60}$  requires a lot of computing power and significant amount of time.

$> 2^{100}$  infeasible, for example : it is impossible to find different keys with non quantum computers.

4/0 / 2025

# Functions

function/mapping/map  $f : X \rightarrow Y$  consists of domain  $X$  and codomain  $Y$  and a rule which assigns

**image**  $y = f(x) \in Y$  for **every input element**  $x \in X$ .

The set of all  $f(x)$  is a subset of  $Y$  and called **range**.

Any  $x \in X$  with  $f(x) = y$  is called a **preimage** of  $y$ .

Let  $B \subset Y$  then we say that  $f^{-1}(B) = \{x \in X : f(x) \in B\}$ .

the **preimage/inverse image of  $B$  under  $f$** .

Note : A mathematical function is not the same as an algorithm.

An algorithm is a step by step and possibly recursive procedure which produces an output from a given input.

There can be different algorithms or no known algorithm for a given mathematical function.

For example, the function  $f(x) = x^2$  can be computed by different algorithms.

Also algorithms can use random data making sure they have different behaviour on different runs of the same algorithm.

For example, the function  $f(x) = x^2$  can be computed by different algorithms.

Also algorithms can use random data making sure they have different behaviour on different runs of the same algorithm.

For example, the function  $f(x) = x^2$  can be computed by different algorithms.

Also algorithms can use random data making sure they have different behaviour on different runs of the same algorithm.

## Different types of function

Every set has an identity function,  $id_X : X \rightarrow X$  mapping each  $x \in X$  to itself.

Functions can be **composed** if the range of the first function lies within the domain of the second function.

Let  $f : X \rightarrow Y$  and  $g : Y \rightarrow Z$  be functions, then  $g \circ f$  is a composite function

$g \circ f : X \rightarrow Z$  defined as  $g \circ f(x) = g(f(x))$

Let  $f : X \rightarrow Y$  be a function, then  $f$  is **injective** or **one-one/1-1** if different elements of the domain map to different elements of the range, i.e.

$\forall x_1, x_2 \in X$ , with  $x_1 \neq x_2$  we have  $f(x_1) \neq f(x_2)$

## Different types of function

Equivalently,  $\forall x_1, x_2 \in X \ f(x_1) = f(x_2) \Rightarrow x_1 = x_2$

A function  $f : X \rightarrow Y$  is **surjective/onto** if every element of the codomain  $Y$  is contained in the image/range of  $f$ , i.e.  $im(f) = Y$ .

$f$  is **bijective** if it is both injective and surjective.

A bijective function possesses an inverse map  $f^{-1} : Y \rightarrow X$  such that  $f^{-1} \circ f = id_X$  and  $f \circ f^{-1} = id_Y$ .

Such functions are called **invertible**.

Bijective maps play an important role in ciphering. An encryption map  $E$  must have a corresponding decryption map  $D$  s.t.  $D \circ E = id_M$ , the identity map on the plaintext space  $M$ .

An encryption map has to be injective and decryption has to be surjective. Ciphering is often a composition of several operations, each of them not necessarily bijective, but their compositions are ultimately bijective.

4/0 /2025

## Different types of function

Let  $f : X \rightarrow Y$  be a map between finite sets. Then,

If  $f$  is injective then  $|X| \leq |Y|$ .

If  $f$  is surjective then  $|X| \geq |Y|$

If  $f$  is bijective then  $|X| = |Y|$

If the function is from the same set to itself we call it **permutation**.

4/0/2025

## Different types of function

Let  $f : X \rightarrow Y$  be a map between finite sets. Then,

If  $f$  is injective then  $|X| \leq |Y|$ .

If  $f$  is surjective then  $|X| \geq |Y|$

If  $f$  is bijective then  $|X| = |Y|$

Note that all are necessary and not sufficient.

If the function is from the same set to itself we call it **permutation**.

4/0 / 2025

# Pigeonhole principle

If  $|X| > |Y|$  then  $f$  is not injective.

Suppose  $X$  is a set of some pigeons and  $Y$  a set of holes. If there are more pigeons than holes, then if you are trying to map all the pigeons in  $X$  to some hole (which is what a function does), then at least one hole has  $> 1$  pigeon.

4/0 /2025

# Relations

A binary relation/relation between  $X$  and  $Y$  is a subset  $R \subset X \times Y$ . I.e. It is a set of pairs  $(x, y)$ ,  $x \in X$  and  $y \in Y$ .

A function  $f : X \rightarrow Y$  defines a relation between  $X$  and  $Y$ .  
 $R = \{(x, y) \in X \times Y : y = f(x)\}$ .

$R$  contains all tuples  $(x, f(x))$  with  $x \in X$ .

**Equivalence relation** on a set  $X$  are special relations that induce a partition on  $X$ .

4/0 / 2025

# Relations

Let  $R$  be a relation on  $X$ , then  $R$  is called an **equivalence relation** if it satisfies the following conditions:

$R$  is reflexive, i.e.  $(x, x) \in R, \forall x \in X$

$R$  is symmetric, i.e. if  $(x, y) \in R$  then  $(y, x) \in R$

$R$  is transitive i.e. if  $(x, y) \in R$  and  $(y, z) \in R$  then

If  $R$  is an equivalence relation and  $(x, y) \in R$  then  $x$  and  $y$  are called equivalent and we write  $x \sim y$ .

For  $x \in X$ , the subset  $\bar{x} = \{y \in X : x \sim y\} \subseteq X$  is called the **equivalence class of  $x$**  and all elements in  $\bar{x}$  are related to  $x$  by  $R$ .  
of that class.

**The equivalence classes are disjoint and their union is  $X$ .**

The set of equivalence classes is the quotient set  $X/R$ .

4/0 / 2025

# Equivalence Classes

The elements of  $X / \sim$  are sets, but sometimes we use the same  $x$  to represent both an element of  $X$  and one of its equivalence classes. Correct notation is  $[x]$ .

We define an equivalence relation  $R_2$  on  $X = \mathbb{Z}$ :

$$R_2 = \{(x, y) \in \mathbb{Z} \times \mathbb{Z} : (x - y) \in 2\mathbb{Z}\}$$

i.e. pairs  $(x, y) \in R_2$  have the property that their difference  $(x - y)$  is even, i.e. divisible by 2.

$(2, 4), (3, 1), (-1, 5)$  are all elements of  $R_2$  but  $(0, 1), (-3, 4) \notin R_2$

**Exercise –  $R_2$  is an equivalence relation.**

4/0 / 2025

# Equivalence Classes

The equivalence class of  $x \in \mathbb{Z}$  is  $[x]$  or  $\bar{x}$  is  $\{\dots, (x-4), (x-2), x, (x+2), (x+4), \dots\}$ .

There are only two different equivalence classes:

$$\bar{0} = \{\dots, -4, -2, 0, 2, 4, \dots\}$$

$$\bar{1} = \{\dots, -3, -1, 1, 3, 5, \dots\}$$

I.e.  $\bar{2} = \bar{0} = \bar{2}$  and  $\bar{1} = \bar{1} = \bar{3}$ .

$\mathbb{Z}/\sim$  only has two elements, which is often denoted  $\mathbb{Z}/\langle 2 \rangle$ ,  $GF(2)$  or  $\mathbb{F}_2$ , field of residue classes modulo 2, be "identified" with the binary set  $\{0, 1\}$ .

4/0/2025

## Residue Classes modulo

Can we generalize to residue classes modulo  $n$ . Let  $n \geq 2$ .

Consider  $R_n$  on  $X = \mathbb{Z}$ ,

$$R_n = \{(x, y) \in \mathbb{Z} \times \mathbb{Z} : x - y \in n\mathbb{Z}\}$$

It is an equivalence relation. There are  $n$  different residue classes and thus  $\mathbb{Z}/\sim$  has  $n$  elements.

We call this set the **residue classes modulo  $n$**  or **integers modulo  $n$**  and denote it as  $\mathbb{Z}_n$  or  $\mathbb{Z}/(n)$ .

Each residue class has a standard representative in  $\{0, 1, \dots, n-1\}$  and elements in the same residue class are called **congruent modulo  $n$** .

4/0 / 2025

# Fields

A field is a set with two binary operations – called addition and multiplication – which satisfy field axioms:

- Associativity of addition and multiplication
- Commutativity of addition and multiplication
- Additive and multiplicative identity exist
- Additive inverse exists
- Multiplicative inverse exists for all non zero elements
- Distributivity

A field is a commutative ring where  $0 \neq 1$  and all non zero elements are invertible under multiplication.

Residue classes modulo 2 form a field. **Exercise – Do residue classes modulo  $n$ , for any  $n \in \mathbb{N}$  form a field?**

4/0 /2025

## Exercises in this class

Show that  $R_2$  is an equivalence relation.

Do residue classes modulo  $n$ , for any  $n \in \mathbb{N}$  form a group? If yes, why? If no, then what conditions on  $n$  make

$a \equiv c \pmod n$  iff  $[a] = [c]$ .

Any two congruence classes mod  $n$  are either equal or disjoint.

There are exactly  $n$  congruence classes modulo  $n$ :  
 $[0], [1], \dots, [n-1]$ .

Prove that for  $\mathbb{Z}/n\mathbb{Z}$ , the binary operations  $+$  and  $\cdot$  modulo  $n$  are **well-defined**.

4/0 / 2025

# Modular Exponentiation

Lets work in  $\mathbb{Z}/100\mathbb{Z}$ .

$$2^2 = 4$$

$$2^4 = (2^2)^2 \equiv 4^2 \equiv 16 \pmod{100}$$

$$2^8 = (2^4)^2 \equiv 16^2 \equiv 56 \pmod{100}$$

$$2^{16} = (2^8)^2 \equiv 56^2 \equiv 36 \pmod{100}$$

$$2^{32} = (2^{16})^2 \equiv 36^2 \equiv 4 \pmod{100}$$

$$2^{64} = (2^{32})^2 \equiv (4)^2 \equiv 16 \pmod{100}$$

Now  $100 = 64 + 32 + 4$  so

$$2^{100} = 2^{64} \cdot 2^{32} \cdot 2^4 \equiv 16 \cdot \dots \cdot (4) \cdot 16 \equiv 76 \pmod{100}$$

$2^{100} \equiv 76 \pmod{100}$ , and this requires only  $6 + 3$  multiplications instead of 100.

It is possible to calculate  $a^N \pmod{n}$  using only  $c$  multiplications for some constant  $c$ . This means to calculate  $a^N$  even if  $N$  is very large and has thousands of digits.

4/0 / 2025

# Application – Diffie Hellman Key Exchange

How does Alice and Bob establish a secret key in place without meeting beforehand?

We know that given  $a$  and  $N$  it is easy calculate

But given  $a^N \bmod n$  and  $a$  it is very hard to find  $N$ .  
of the discrete logarithm problem.

Why call it logarithm? Because over  $\mathbb{R}$  if  $a^N = b$  then  $N = \log_a(b)$ .

But this is easy to do over  $\mathbb{R}$  but over natural numbers  $\bmod n$  it is not easy to find "logs".

4/0 / 2025

# Application – Diffie Hellman Key Exchange

If  $2^N \equiv 3 \pmod{11}$ , find  $N$ . We have to try out all  $N$  and  $N = 8$ .

What if  $N$  and  $n$  are  $10^{100}$  then its a hopeless task.

The Key Exchange algorithm:

Alice and Bob publicly choose a large prime  $p$  and

Alice secretly chooses a number  $s$  and sends  $a^s \pmod{p}$  to Bob.

Bob secretly chooses a number  $t$  and sends  $a^t \pmod{p}$  to Alice.

Alice computes secretly  $(a^t)^s \pmod{p}$  and Bob secretly computes  $(a^s)^t \pmod{p}$ .

The shared key is  $a^{st} \pmod{p}$ .

4/0 /2025

# Application – Diffie Hellman Key Exchange

Alice and Bob should not reveal  $s, t, k$  to anyone.  
Eve can see  $a^s$  and  $a^t$  but cannot find  $s$  or  $t$  to compute  $k$ .  
Note that there is no information theoretic security.  
Given ample time Eve can also find  $s, t$ . We have chosen  $p$  is very large so that the running time is trillions of years.  
Effectively  $k$  is safe.

4/0 / 2025

## Inverses in $\mathbb{Z}/n\mathbb{Z}$

Let  $a \in \mathbb{Z}/n\mathbb{Z}$ . A solution  $x \in \mathbb{Z}/n\mathbb{Z}$  of the equation

$$ax \equiv 1 \pmod{n}$$

is called **inverse of  $a$  mod  $n$**  and denoted as  $a^{-1}$ .

**$a$  is invertible in  $\mathbb{Z}_n$  iff  $\gcd(a, n) = 1$ .**

$a$  is invertible implies  $\exists x \in \mathbb{Z}_n$  s.t.  $ax \equiv 1 \pmod{n}$

This is true if and only if  $\exists y \in \mathbb{Z}$  s.t.  $ax + ny = 1$

But the above equation is solvable for  $x$  and  $y$  iff

– Exercise! (Hint : Use **Extended Euclidean Algorithm**)

Exercise – Let  $p$  be a prime number, then every non-zero element  $\mathbb{Z}_p$  is invertible.

This makes  $\mathbb{Z}_p$  similar to real numbers, it is also a field.

We will discuss Euler Totient function, Fermat's theorem, CRT later in the course.

4/0 / 2025

# Complexity Classes

conservative approach to computing devices, a  
efficient computations with the complexity class  $P$ .

In cryptography we take a more liberal approach  
computing devices to be randomized.

**Complexity Class P:** language  $L$  is **recognizable**  
**polynomial time** if there exists a deterministic Turing  
 $M$  and a polynomial  $p(\cdot)$  s.t.

on input a string  $x$ , machine  $M$  halts after at most  $p(|x|)$  steps  
and

$M(x) = 1$  if and only if (iff)  $x \in L$ .

$P$  is the class of languages/problems that can be solved in  
deterministic polynomial time.

# Complexity Classes

NP : complexity class  $NP$  associated with computational problems with solutions that once given can be checked for validity.

Is also sometimes defined as class of languages that can be recognized by a non-deterministic polynomial time TM.

More formally, a language  $L$  is in  $NP$  if there exists a polynomial time relation  $R \subseteq \{0,1\}^* \times \{0,1\}^*$  and a polynomial  $p$  such that  $L$  can be recognized in deterministic polynomial time iff  $\exists y$  s.t.  $|y| \leq p(|x|)$  and  $(x, y) \in R$ .

Such a  $y$  is called a **witness for membership** of  $x$  in  $L$ .

Thus  $NP$  consists of the set of languages for which there exist short proofs of membership that can be efficiently checked.

It is widely believed  $P \neq NP$ .

4/0 / 2025

## Complexity Classes

**NP-completeness:** language is NP-complete if and every language in  $NP$  is **polynomially reducible**

**What does polynomial reduction mean?** language polynomially reducible to a language  $L'$  if there exists polynomial time computable function  $f$  s.t.  $x \in L \iff f(x) \in L'$ .

Note : This implies  $L'$  is at least as hard as  $L$ , i.e.  $L'$  is at least as difficult than  $L$ .

If you have a way of solving for  $L'$  then we can use  $f(x)$  and solve for  $x \in L$  or not.

Example : Satisfiability of formula, graph colouring, hamiltonicity.

In the above definition if the problem does not have a polynomial time solution then we get **NP-hard**. So in some sense, NP-hard is the hardest problem in NP.

4/0 / 2025

## Randomized Algorithms

We present a simple randomized algorithm – algorithm that uses random bits in logic or procedure – for deciding whether or not a given undirected graph is connected.

Interesting because it uses significantly less space than standard BFS or DFS based deterministic algorithms.

There may or may not be error in the outputs of randomized algorithms (Las Vegas algorithms give correct outputs, Monte Carlo algorithms have a probability of error, Miller Rabin primality test.)

Whether or not a graph is connected is easily reduced to testing **connectivity between any pair of vertices**.

Space complexity is reduced because only two vertices are stored.

Time complexity is high since we need to invoke the vertex tester  $C(n, 2)$  times, where  $n$  is the number of vertices.

4/0 / 2025

## Randomized Algorithms

On input  $G = (V, E)$  and two vertices  $s, t$  we take a **walk of length  $\mathcal{O}(|V||E|)$  starting at  $s$**  and test whether or not  $t$  is encountered.

If  $t$  is encountered then algorithm will accept, else reject.

By random walk, we mean that at each step we randomly select one of the edges incident at the current vertex and traverse the edge to the other end point.

Clearly, if  $s$  is not connected to  $t$  in  $G$  the probability the algorithm will accept is 0.

The harder part is to **prove that if  $s$  is connected to  $t$  the algorithm will accept with probability  $\geq 2/3$** .

Either way the algorithm will error with probability  $\leq 1/3$ . This error can be brought down further by running the algorithm multiple times.

4/0 / 2025

## Randomized Algorithms

Outcome of internal coin tosses as a transition of by  $(\langle state \rangle, \langle symbol \rangle, \langle direction \rangle)$  instead of  $(\langle state \rangle, \langle symbol \rangle)$  with each direction having equal probability.

Or view the outcome of internal coin tosses as an additional input.

**Probabilistic Polynomial Time Turing Machine** is a probabilistic machine that always – independent of the outcome of its internal coin tosses – halts after a number of steps in the length of the input – number of steps.

It also follows that the coin tosses for a PPT TM can be simulated by a polynomial in its input length.

4/0 /2025

# Associating Efficient Computation BPP

We want to consider only **efficient randomized algorithms**, which the running time is bounded by a polynomial length of the input.

This is captured by the complexity BPP, **bounded polynomial time**.

Formally, we say that  $L$  is recognized by the PPTM

$\forall x \in L$  it holds that  $Pr[M(x) = 1] \geq 2/3$  and

$\forall x \notin L$  it holds that  $Pr[M(x) = 0] \geq 2/3$ .

BPP is the class of languages that can be recognized by a probabilistic polynomial time TM.

Is  $BPP = P$ ? Open question!

No relation between BPP and NP is known!

4/0 / 2025

## Size of integer

Relation between positive integer  $n$  and its size  
 $size(n) = \lfloor \log_2 n \rfloor + 1$ .

The size of an integer is the number of bits that represent it.

Let  $n = 10^{24}$ ,  $size(n) = \lfloor 24 \log_2 10 \rfloor + 1 = 80$  bits.

Unary representation will need  $10^{24}$  bits to represent the number, not efficient.

Consider the algorithm that finds the prime divisors of integer  $n$ . We can use an algorithm that does division by odd positive integers  $\leq \sqrt{n}$ .

The number of divisors is at most  $\lfloor \frac{1}{2} \sqrt{n} \rfloor$ , and since  $\sqrt{n} = 2^{\frac{\log_2 n}{2}}$ , the worst case running time is  $\mathcal{O}(2^{\frac{\log_2 n}{2}})$ , subexponential.

Note that  $\frac{1}{2}$  in the exponent can not be removed in asymptotic notation.

4/0 / 2025

# Discrete Probability

We consider discrete probability spaces here. Let  $\Omega$  be a countable set,  $\mathcal{S} = \mathcal{P}(\Omega)$ , the powerset of  $\Omega$  and  $Pr : \mathcal{S} \rightarrow [0, 1]$ , a function with the following properties:

$$Pr[\Omega] = 1.$$

If  $A_1, A_2, A_3, \dots$  are pairwise disjoint subsets of  $\Omega$  then

$$Pr[\cup_i A_i] = \sum_i Pr[A_i].$$

The triple  $(\Omega, \mathcal{S}, Pr)$  is called a discrete probability space.  $\Omega$  is called the sample space,  $Pr$  the discrete probability distribution on  $\Omega$ .

The subsets  $A \in \mathcal{S}$  are said to be events and  $Pr[A]$  the probability of  $A$ .

4/0 /2025

# Uniform Distribution

The sets/events in the second condition are either a finite number or countably infinite, since all probabilities are non-negative and bounded by 1, the series converges.

**Uniform Distribution:**  $Pr$  is a uniform distribution if all singleton events have equal probability, i.e.  $Pr[\{\omega\}] = \frac{1}{|\Omega|}$  for all  $\omega \in \Omega$ .

Examples include a fair coin or fair dice. Random number generators should produce uniformly distributed random numbers.

In cryptographic algorithms we assume a key is chosen uniformly at random so that all possible keys have equal probability.

4/0 / 2025

# Independent Events

Let  $A, B$  and  $A_1, A_2, \dots, A_n$  be events in a probability space.  $A$  and  $B$  are said to be **independent** if the joint probability equals the product of probabilities,

$$Pr[A \cap B] = Pr[A]Pr[B].$$

$A_1, A_2, \dots, A_n$  are **mutually independent** if for every subset of indices,  $\mathcal{I} \subset \{1, \dots, n\}$  one has

$$Pr[\cap_{i \in \mathcal{I}} A_i] = \prod_{i \in \mathcal{I}} Pr[A_i].$$

Note that **mutual independence of  $n$  events** is stronger than **pairwise independence of all pairs**.

4/0 / 2025

# Mutually independent events Vs Pairwise independent

Let  $X_1$  and  $X_2$  be two binary random variables (we will discuss RVs more formally soon) that are given by tossing two fair coins so that  $X_1$  and  $X_2$  are independent.

Let  $X_3 = X_1 \oplus X_2$ .

Then  $X_1, X_2, X_3$  are pairwise independent and each  $X_i$  has a uniform distribution, **but they are not mutually independent.**

$Pr[X_1 = 1 \wedge X_2 = 1 \wedge X_3 = 1] = 0$ , since  $X_3$  must be 0 if  $X_1 = X_2 = 1$ .

But  $Pr[X_1 = 1] \cdot Pr[X_2 = 1] \cdots Pr[X_3 = 1] = \frac{1}{2}^3$

4/0/2025

# Conditional Probability

Let  $A$  and  $B$  be two events in a probability space such that  $Pr[A] \neq 0$ . Then the conditional probability given  $A$  is defined by

$$Pr[B|A] = \frac{Pr[A \cap B]}{Pr[A]}.$$

Note:  $Pr[B|A] = Pr[B]$  iff  $A$  and  $B$  are independent.

4/0/2025

# Random Variables

The sample space of a probability space is often a standard space and in particular to real number map is called a **random variable**.

Let  $Pr : \Omega \rightarrow [0, 1]$  be a discrete probability distribution function  $X : \Omega \rightarrow \mathbb{R}$  is called a **real random variable**.

For any  $x \in \mathbb{R}$  one obtains an event  $X^{-1}(x) \subset \Omega$  probability  $Pr[X = x]$  is defined by  $Pr[X^{-1}(x)]$ .

$p_X : \mathbb{R} \rightarrow [0, 1]$  is defined by  $p_X(x) = Pr[X = x]$  **probability mass function/pmf** of  $X$ .

**Cumulative distributive function**  $F : \mathbb{R} \rightarrow \mathbb{R}$  is defined by  $F(x) = Pr[X \leq x]$ .

$X$  induces a discrete probability distribution  $Pr_X$  on a countable subset  $X(\Omega) \subset \mathbb{R}$ , with the sample space being a subset of  $\mathbb{R}$ .

4/0 / 2025

## Random Variables

Let  $X_1, X_2, \dots, X_n$  be random variables on discrete space with pmf  $p_{X_1}, p_{X_2}, \dots, p_{X_n}$ . The random variables are called **mutually independent** if for any sequence  $x_1, x_2, \dots, x_n$

$$Pr[X_1 = x_1 \wedge X_2 = x_2 \wedge \dots \wedge X_n = x_n] = p_{X_1}(x_1) \cdot p_{X_2}(x_2) \cdot \dots \cdot p_{X_n}(x_n)$$

Let  $\mathcal{X} = \{0, 1\}^n$  be a space of plaintext and ciphertext. Assume the plaintexts  $X$  are uniformly distributed. Let  $Y = \pi(X)$  be a bit permutation. i.e. only positions are permuted. If we assume  $Y = \pi(X)$  as the ciphering algorithm, we see that  $Y$  is also uniformly distributed.

Are  $X$  and  $Y$  mutually independent? i.e. is  $Pr[X = m \wedge Y = c] = Pr[X = m] \cdot Pr[Y = c]$   $\forall x \in \mathcal{X}, y \in \mathcal{Y}$ ?

No! if  $m$  and  $c$  have a different number of 1s then  $Pr[X = m] \neq Pr[Y = c]$  since it is impossible for a bit permutation. Thus  $\pi$  is not a secure cipher.

# Random Numbers

Random numbers/ random bits play an important role in cryptography.

Keys (or seeds for the keys) are chosen uniformly and many cryptographic algorithms are probabilistic and require random inputs.

**random bit generator (RBG)** is a mechanism/device that generates a sequence of random bits, s.t. the corresponding sequence of binary random variables  $X_1, X_2, X_3, \dots$  has the following properties:

$Pr[X_n = 0] = Pr[X_n = 1] = \frac{1}{2}, \forall n \in \mathbb{N}$  (uniformity)  
 $X_1, X_2, \dots, X_n$  are mutually independent for all  $n$ .  
For any subset of indices we consider the probability is the product of the individual probabilities.

Some sequences which are NOT uniformly random:  $X_3 = X_1 \oplus X_2$ . So obvious ways to stretch a given seed cannot be used.

# Random Numbers

Generated manually by coin tossing or die rolling  
hardware that uses physical phenomena such as t  
or electrical noise as inputs.

But they are slow, elaborate and/or costly.

There are fast all digital random bit generators o  
processor chips which use thermal noise but whet  
trust them or if they have a backdoor is disputed

The generation of random bits is basically equiva  
generation of random integer numbers.

# Birthday Paradox

Random numbers match surprisingly often, **the birthday paradox.**

Assume there are 23 people in the a room. Then the probability that at least two of them have their birthday on the same day of the year is  $> 50\%$ .

Intuitively we would have thought for that to happen  $\approx \lfloor \frac{365}{2} \rfloor$  people in the room.

Why is this so? Let  $p$  be the probability that no match occurs, i.e. all birthdays are different.

Claim :  **$p$  decreases exponentially as  $n$  increases.**

For  $n = 2$ ,  $p = \frac{364}{365} = 0.99726$ . For  $n = 3$ ,  $p = \frac{363 \cdot 362}{365 \cdot 364} = 0.99179$ .

$n = 9$   $p = .89065$ ,  $n = 13$ ,  $p = 0.79249$ ,  $n = 17$ ,  $p = 0.693$ ,  $n = 20$ ,  $p = 0.57899$ .

For  $n = 23$ ,  $p = 0.493$ . This implies  $1 - p > 0.5$ .

# Birthday Paradox

This is the formal statement: Let  $Pr$  be a uniform on a set of cardinality  $n$ . If we draw  $k = \lceil \sqrt{2 \ln(2)n} \rceil \approx 1.2\sqrt{n}$  independent samples from the probability of a collision is  $\approx 50\%$ .

Consider collision of binary random strings of length  $n$ .

Collisions are expected after around  $\sqrt{2}$  values.

So if the strings are sufficiently long and uniform then the collisions should almost never occur.

This is why we need at least 128 bit lengths for hash functions.
